## 1.0 Summary of last report

The hydro-electric turbine located in the coffee farm at the Dedan Kimathi University was installed in 1980 by Gilbert Gilkes & Gordon Ltd (England). This turbine had mainly the purpose of producing electricity for lighting. After several years the project broke down and the turbine got out of use. The extended period of time of non-usage caused a deplorable state for the turbine. Today there is a project to revive this system that works with a Francis turbine which had the following specifications:

**Table 1:** Specifications for the Francis turbine made in 1926

Power	12.5 KW
Voltage	240 V
Generator speed	1500 rpm

In the last report from March 2016 were three phases described to make this project work:

- Phase 1: Was to determine the viability of the project and to dismantle the turbine system for inspection.
- Phase 2: Servicing the main components of the system i.e. generator and the governor, assembling the turbine system and reworking the foundation for mounting the system.
- Phase 3: To generate more power above the current 12.5 kW (in these case 100kW), ensure an optimal power generating system and ensure the system is sustainable.

Furthermore the results measured in phase 2 were considered as a clear indication that the revival of the system can be successful; see results in table 2.

**Table 2:** Measured parameters in phase 2

Runner speed	350 rpm
Generator speed	1150 rpm
Generator output	210 V

Values such as the head of the turbine and the necessary flow rate of water were calculated to determine the most suitable type of turbine to generate 100kW. After evaluating the possibilities of how to generate more power, the conclusion was to invest in a new type of turbine: a Cink Kaplan Turbine.

In conclusion the costs for the project were estimated and here shown in table 3.

**Table 3** Cost of the Project [1]

Item	Cost (Ksh.)
Civil works	400,000
Cink Kaplan turbine	13, 000, 000
Generator	400,000
Miscellaneous	200,000
<b>TOTAL</b>	<b>14,000,000</b>

## 2.0 Introduction

This project is an extension of the water turbine project as a complement to the previous work on phase 2. Despite the proposal of investing in a new turbine for the farm, there is the intention of reviving the francis turbine for teaching purposes as a training rig for students. Figure 1 shows the turbine allocated at the farm.

**Figure 1.** Francis turbine at the coffee farm [photo, July 2016]

This hydropower system is composed basically of the turbine, the generator and the governing system. On the last phase of the project the focus was on the two first. The remaining component (the governor) has been examined, too, but not tested. Furthermore, the possible investment required for the revival of this part was not included in the budget presented above. Out of these criteria follows that the governing system will have the central role for the project.

## 3.0 Objectives

1. To analyze the working principle of the oil pressure governor and define the steps to reactivate its use.
2. To determine missing components and elaborate the technical drawings for machining.
3. To determine options of combining the old technology with current hydraulic or electric components.

## 4.0 Methodology

The content of the project will need the understanding from the old technology, which we find in the farms governor, to the new technologies that are currently applied in hydropower stations. In order to find the way of combining these two technologies, there will be a closer look into the practice.

1. The first practical look consists in visiting the site in the university where the turbine is located.
  - To understand the working mechanism in the generating system
  - To evaluate the components in their environment and
  - To transport the governor to ADMATC<sup>1</sup> for further inspection of the single components
2. Secondly, visiting the Sagana hydropower station of the Kenya Electricity Generating Company (Kengen) will give us the opportunity to observe the types of governors implemented in their systems. Yet this examples deal with greater power production (around 1,5 MW).
3. At last, we make a few hydraulic exercises to understand the basic components of a hydraulic governor.

## 5.0 The Governor

The mechanic oil pressure governor of the farm was installed by the Gilkes Company. It has following product description: Oil pressure governor, Type A, Nr. 644 (see Figure 2).

**Figure 2.** Gilkes & Gordon Ltd., Oil pressure governor [photo, July 2016]

---

<sup>1</sup> ADMATC: Advanced Design and Manufacturing Training Center, Mechatronics Department, DeKUT

The primary purpose of a governor for a hydroelectric unit is to control the speed deviations and loading of the unit. It accomplishes this by controlling the flow of water through the turbine, which is defined by the opening position of the so called wicket gates. As we can see in Figure 3, the wicket gates are located one “ring” before the runner. The water will flow thru the scroll casing until it hits the wicket gates and then from the runner to the outlet. The reason why a governor system is needed, is to maintain the rotation of the shaft as constant as possible, otherwise the generator will not be able to produce “clean” electrical power.

**Figure 3** Francis turbine – Component overview [3]

From the last report we know about the farms governor, that some parts were missing. Including the hand wheel that was used to open the vanes manually, this was machined in the last phase. For other possible missing parts we contacted the Gilkes Company, to request for information about the assembly parts or datasheets, however with no success since the documents were unable to find. (See appendix nr. 1)

The challenge that follows out of it now, is the understanding of its working principle. This governor was built around 90 years ago, which means we will be dealing with an old mechanism. Without the information of the Company that produced it and limited sources in the internet about this specific governor, we will take as reference the working principle and components from other mechanical governors to describe the functioning system and determine the differences between the newer and the old technology.

## **5.1 General descriptions of a mechanical governor**

There are numerous designs and configurations of mechanical governors, but generally, they have many of the same components. The main parts are a speed sensing device, usually a ball head, an oil pressure system, hydraulic valves to control oil flow, and one or more hydraulic servomotors to move the wicket gates. [6] Now an overview of the components:

### *The Oil Pressure System*

The oil pressure system consists of an oil pump/s, oil accumulator tank/s, oil sump, and the necessary valves, piping, and filtering required

### *The Control System*

The control system can be mechanical, analog, or digital depending on the type of governor. In the truest sense, the control system is the “governor”. The purpose of all other components in a governor system is to carry out the instructions of the control system (governor). For mechanical governors, the control system consists of the flyball, linkages, compensating dashpot, and speed droop device.

### *Hydraulic System*

The hydraulic system consists of an oil sump, one or two oil pumps, an air over oil accumulator tank, and piping to the servomotors. Typically, there are two pumps with lead and lag controls so that there is always a backup pump. Some systems will share two pumps between two units so that in an emergency one pump could be used for both units. The accumulator tank is usually sized so that in the event the pumps fail, the gates can still be closed.

### *Wicket Gate Position Feedback*

The restoring mechanism is a “feedback” device that feeds back the current wicket gate position and the post movement command position to the control system. In a mechanical governor this is typically a pulley cable system.

These descriptions above apply to modern mechanisms of governors and in the background also for former governors, yet with not all of the components. We could find these aspects at the Sagana Falls Power Station of KENGEN. The power station is set for a capacity of 1,5 MW power production.

On their 4 Francis Turbine they had on two of them a hybrid of governors. One of them was an automatic/manual governor and the other one was purely manual, in case the first governor fails. The two governors are located next to each other on one side of the turbine. Both of them are connected to the regulating lever and rod to position the wicket gates.

**Figure 4** Auto/ Manual Governor[photo, Sept. 2016]

**Figure 5** Manual governor [photo, Sept. 2016]

On figure 4 we can see the ball head of the governor (the conic component). This is the flying ball mechanism that is directly driven by the shaft of the turbine.

**Figure 6** Position of rod at under- and over speed [8]

As the shaft rotates the fly weights will expand causing the vertical movement of a rod that varies the position of valves, allowing the oil to flow in different ways in the system. The pushrod is then counterbalanced by a spring. To clarify this, use Figure 6 as a reference to observe the oil flow in case of over- or under speed.

The auto/manual governor also has a servo mechanism that allows an accurate control of the pushrod. This mechanism is not used for the manual governor in figure 5.

Another type of governor we found is the hydraulic governor at the Mesco Hydro Station that produces around 0.43 MW. Here we found the most modern variation of a governor in our visit. This observation is

important for the 3<sup>rd</sup> objective defined before. This governor has a sensitive system connected to the inlet. A 15 KW electromotor is in charge for the oil pumping in the governor. We found several types of directional control valves (DCV) that control the flow of oil and response to regulate the opening of the wicket gates.

*In the library of content of the project, there are photography's contemplating the hydraulic circuit used in the hydraulic governor and also pictures of the other governors we could find at KENGEN.*

## 5.2 Oil Pressure Governor, 1926

Having searched after the common parts in a governor, we want to determine the parts that contained the one in the farm. As a guidance we also used drawings of governors to find a similarity in the structure, nevertheless we point out they are not 100% alike.

**Figure 7** Universal governor of Escher Wyss (Zurich, 1906) [4]

On the first look, we consider the structure of the universal governor (Fig. 7) is the nearest to the one we are dealing with, at least the parts that are contained in it.

We find:

- 1) An oil sump on the lowest part, with two draining sections.
- 2) A booster gear pump (5) connected with a pipeline to the section (7) which conducts the oil to the front and the back of the governor (5)\*<sup>2</sup> and also measures the percentage of the wicket gates' opening.

<sup>2</sup> The five meant here is the one on the left

- 3) A hand wheel (on the right) for manual adjustment.
- 4) A flying ball/weight mechanism (13)
- 5) A bar (11) with the effect of a “see-saw” according to the input speed between (13) and (7). Basically the responding/regulating bar of the input in the system.

Other types of mechanical governors are shown in Figures 9.1 and 9.2.

**Figure 9** Sturges governor (U.S.A, about 1900) [4]

**Figure 9** Pilot unit with integrated fly ball sensor (about 1935) [4]

With the hint we observed in this figures we could define the function of the parts in our governor.

### 5.2.1 Vision

The vision of the project again is to make the turbine work. Since KENGEN engineers state the machine can run again, we put more concrete objectives, in order to fullfill the steps needed to make this governor work, such as.

- Define the missing parts to design and machine them.
- Propose a solution for the broken components

### 5.2.2 Current state

The governor which we are putting the focus on is not in a working condition and neither the connecting parts to the turbine, plus there are missing parts which will be designed and machined.

### 5.2.3 Actions

We took a closer look into the system, to define the missing parts and give maintenance to them.

For practical reasons the single components were measured and then designed in a CAD-Software: Autodesk Inventor 2015 (See appendix 2; *note: the files can only be open with the 2015 version or a higher one; The pieces are contained also in the library of the project*).

**Figure 10** Single components of the governor [photo, sept. 2016]

The whole governor was cleaned with an industrial cleaner to remove the old oil and dirt stored in it. Before reassembly all rackets were changed for new ones.

#### 5.2.4 Test

The testing of the governor we define as an open milestone, since it can be tested properly when the missing parts are machined. In other words, the governor itself is ready to be tested, but is waiting for the new components to be attached.

### 5.3 Structure and Components

While we were reassembling the components, we noted and described the working principle of this governor, which is explained in the following points:

*Note: for explaining we define the face of the governor with the hand-wheel as the front face. See appendix 4.*

- 1) From the outside we find a machine with an input and an output. The input speed follows thru a transamition with a belt from the output shaft of the turbine to the input pulley of the governor. See Figure 11. The output is shown in Figure 12.

**Figure 11** Components at the input

- 2) There is a booster gear pump also driven by the input shaft. The rotating gear can be appreciated in figure 11, which is coupled to another gear of the same size. *The location of it can be seen in figure 13.*
- 3) The housing itself is the oil sump, divided into the lower and the upper part.
- 4) The hand wheel is used to adjust the angle position of the outputting shaft (the manual adjustment).

**Figure 12** Governor from the inside: piston movement and oil flow

- 5) Figure 12 shows also the flow of oil, which helps the operator (the person) to move easily the piston back and forth with the hand wheel. As the hand wheel rotates, the angle position on the output shaft changes. This is coupled to the turbine thru the regulating rod and lever of the wicket gates, which finally regulates the water flow that goes into to the rotor.
- 6) On the left the oil meter is positioned direct to the lower oil sump and connected to the input shaft thru a 5 mm-pipe.
- 7) On the right we find a component directly connected to the lower oil sump with no connection parts. Comparing it to the universal governor, we conclude there is a missing pipe for oil flow that fits to it and to one of the entries of the gear pump. See the location in Figure 13.

**Figure 13** Missing Pipe [photo, Sept. 2016]

This governor is purely manual with a “primitive sensing system” in comparison to the current ones or rather without one, since it can not sense the flow rate variations. It gets the input directly from the output shaft of the turbine and cannot adjust by itself the opening of the wicket gates. Nevertheless it fulfills its working purpose by positioning the wicket gates to a defined level by the operator.

## 6. State of components

### 6.1 At the governor

Missing components:

1. The oil flow pipe
2. Plugs for the openings at the pump section (see fig. 14)
3. Threaded bolts
4. Connecting component for the measuring stock attached to the dashpot cylinder

**Figure 14** Missing parts

## 6.2 At the turbine

Missing components:

1. Rods for the guide valve ring (see Figure 14-ii).
2. Pins for the rods in 1. (see Figure 14-iii)

Damaged components:

1. Regulating lever (see Figure 14-i and Figure 15)

**Figure 15** i-Damaged lever; ii-Missing Rods; iii-Missing pins

**Figure 16** Closer look to the damaged lever

### 6.3 Construction measures

For the construction measures we took in count the financial aspect, for which we decided to present solutions that can be machined at the Machine Shop in ADMATC. Excluding the participation of an extern company would mean that the costs will rely on:

- Material costs
- Machine operation costs
- Personal costs

Furthermore we consulted the personal of the Machine Shop about the feasibility of the components and the compensation proposal that were presented.

The drawings and part lists can be found under appendix 5.

*Note: the drawings until this phase were ready-made but not controlled or proved by a second constructor. Yet the construction proposals were accepted by the machine shop personal.*

## **7. Summary and Project Results**

The revival of the turbine will follow without the services of Gilkes, with the governor and without connection to the grid.

### **The Governor**

The governor regulates the speed of the runner. This is done by controlling the volume of water hitting the runner. By opening the vanes in the turbine cavity more water flows into the runner there by increasing its speed. Consequently if the vanes are closed, the amount of water hitting the runner is reduced considerably and this reduces the speed of the runner shaft.

### **State**

The governor which we are putting the focus on is not in a working condition and neither the connecting parts to the turbine, plus there are missing parts which will be designed and machined.

### **Actions**

Cleaning and oiling of the governor components, changing the rackets, defining missing parts in the governor and at the turbine, designing of the governor in Inventor and elaborating the technical drawings of missing and damaged components for machining in ADMATC.

### **Perspective**

The components missing can be machined in the Machine shop of the University. Once the components are machined, the governor can be tested. For it to be tested at the site of the turbine there should be maintenance works on the linkages to the turbine since they show a rusted surface. The components should be oiled, too.

### **Observation**

For the objectives set at the beginning of the project, we could conclude a very important part for the governor's revival, which include:

- Describing its working principle
- Determining missing and broken parts
- Preparing of the material needed for machining or repairing relevant components

Since we put the focus on the construction, the objective of finding a way to combine the governor with an electric-hydraulic circuit remains open.

<b>Overview of activities during the summer project:</b>	
<b>Week 1 (Th., Fr.)</b>	
Orientation days	International Office, Public Relations, Dean of Students...
<b>Week 2</b>	
Introduction at the Mechatronics Department,	Staff, Lab and Project Supervisor and Dean, School of Engineering: Dr. Jean Bosco
Hydraulics at ADMATC (Advanced Manufacturing and Design Training Center)	Basic hydraulics LAP (Learning Activity Packet) on the AMATROL 850 Series hydraulic trainer: LAP1 Hydraulic power systems LAP2 Basic hydraulic circuits LAP3 Principles of hydraulic pressure LAP4 Hydraulic speed control
Visit to University farm	This is the location of the francis turbine and governor.
<b>Week 3</b>	
Transportation of the governor	From the farm to ADMATC
Dismantling the governor	Opening of the governor to understand its working principle
	Introduction to Prof. Muchiri, Director of the University in Nairobi Campus
<b>Week 4</b>	
Hydraulics at ADMATC	Basic hydraulics LAP: LAP 5 Pressure control circuits
Hydraulics at ADMATC	Intermediate hydraulics LAP: LAP 1 hydraulics DCV applications
Visit to KenGen (Kenya Electricity Generating Company )	Sagana Falls Power Station, 1,5MW Mesco Hydro Station, 0.43MW
<b>Week 5</b>	
Analysis PU Circuit	Describing and understanding the hydraulic circuit applied for the governing system at the Mesco Hydro Station
Governor 3D - Modeling	Measurement and Design of the single Components
<b>Week 6</b>	
Farm	Measurement of broken components at the turbine site
Governor 3D - Modeling	Elaboration of technical drawings
<b>Week 7</b>	
Construction	Reparation of the casting component in the turbine
<b>Week 8</b>	
Maintenance of the Governor	-Cleaning and oiling of the single components, -Changing of rackets -Reassembly of the machine
Final phase:	Handover of the: Report, technical drawings and 3D-Model

## Vocabulary

### English

bar  
bolt  
booster gear  
bushing  
crank  
detent
